      The present sequence represents a representative HIV-1 Nef-Tat-His protein. The protein is used in the creation of the fusion proteins of the invention, in conjunction with a fusion partner (e.g. protein D). The fusion protein can be used in a vaccine to prevent HIV infection.

```
The present sequence represents a His-tagged Nef-Tat linked protein of HIV. The protein is expressed in the yeast Pichia pastoris, and is used to produce the vaccine of the invention. The specification describes the use of HIV Tat, HIV Nef, or Nef-Tat; and HIV gpl20 in the manufacture of a vaccine. The vaccine is used for the prophylatactic or therapeutic immunization of humans against HIV. Tat, Nef or Nef-Tat act in synergy with gpl20 in the treatment and prevention of HIV. The act in vaccine she HIV viral load in HIV infected humans and results in amintenance of CD4+ levels over those levels found in the absence of vaccination with HIV Tat, Nef or Nef-Tat and HIV gpl20.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             120

                                                                                                                                                                                                                                                                                                                                                                ö
                                                                                                                                                                        The present sequence represents a His-tagged Nef-Tat linked protein of HIV, with a lipidation signal sequence (LipoD) which is removed after processing and a Proto fusion partner. The protein is expressed in Escherichia coli, and is used to produce the vaccine of the invention. The specification describes the use of HIV Tat, HIV Nef, or Nef-Tat; and HIV 9D120 in the manufacture of a vaccine. The vaccine is used for the prophylactic or therapeutic immunization of humans against HIV. Tat, Nef or Nef-Tat act in synergy with 9p120 in the treatment and prevention of HIV. The vaccine reduces the HIV viral load in HIV infected humans and results in a maintenance of CD4+ levels over those levels found in the absence of vaccination with HIV Tat, Nef or Nef-Tat

The present sequence represents a His-tagged ProtD-Nef-Tat fusion protein. The protein is expressed in Escherichia coli, and is used to produce the vaccine of the invention. The specification describes the use of HIV Tat, HIV Nef, or Nef-Tat; and HIV gp120 in the manufacture of a vaccine. The vaccine is used for the prophylactic or therapeutic immunization of humans against HIV. Tat, Nef or Nef-Tat act in synergy with gp120 in the treatment and prevention of HIV. The accordance the HIV Intal load in HIV infected humans and results in a maintenance of CD4+ levels over those levels found in the absence of vaccination with HIV Tat, Nef or Nef-Tat and HIV gp120.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       LEWRFDSRLAFHHVARELHPEYFKNCTSEPVDPRLEPWKHPGSQPKTACTNCYCKKCCFH 240

The present sequence represents a representative HIV-1 mutant Tat-His protein. The protein is used in the creation of the fusion proteins of the invention, in conjunction with a fusion partner (e.g. protein D). The specification also describes fusion proteins, comprising HIV-1 Nef protein. The fusion protein can be used in a vaccine to prevent HIV
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            LEWRFDSRLAFHHVARELHPEYFKNCTSEPVDPRLEPWKHPGSOPKTACTNCYCKKCCFH 240

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   The present sequence represents a His-tagged mutant His protein of HIV. The protein is expressed in the yeast Pichia pastoris, and is used to produce the vaccine of the invention. The specification describes the use of HIV Tat, HIV Nef, or Nef-Tat; and HIV gpl20 in the manufacture of a vaccine. The vaccine is used for the prophylactic or therapeutic immunization of humans against HIV. Tat, Nef or Nef-Tat act in synergy with gpl20 in the treatment and prevention of HIV. The vaccine reduces the HIV viral load in HIV infected humans and results in a maintenance of CD4+ levels over those levels found in the absence of vaccination with HIV Tat, Nef or Nef-Tat and HIV gpl20.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  120

The protein is exemplifies the fusion proteins of the invention. The specification also describes fusion proteins comprising HIV-1 Tat protein. The fusion protein can be used in a vaccine to prevent HIV infection.

The present sequence represents a His-tagged Nef protein of HIV, with a lighdation signal sequence (LipoD) which is removed after processing. The protein is expressed in Escherichia coli, and is used to produce the vaccine of the invention. The specification describes the use of HIV Tat, HIV Nef, or Nef-Tat; and HIV gpl20 in the manufacture of a vaccine. The vaccine is used for the prophylactic or therapeutic immunization of humans against HIV. Tat, Nef or Nef-Tat act in synergy with gpl20 in the treatment and prevention of HIV. The

The protein is exemplifies the fusion proteins of
 HIV viral load in HIV infected humans and results CD4+ levels over those levels found in the absence HIV Tat, Nef or Nef-Tat and HIV gp120.

                                                                                                                                                                                                                                            ï
                                                                 The present sequence represents a His-tagged ProtD-Nef fusion protein. The protein is expressed in Escherichia coli, and is used to produce the vaccine of the invention. The specification describes the use of HIV Tat, HIV Nef, or Nef-Tat, and HIV gpl20 in the manufacture of a vaccine. The vaccine is used for the prophylactic or therapeutic immunization of humans against HIV. Tat, Nef or Nef-Tat act in synergy with gpl20 in the treatment and prevention of HIV. The vaccine reduces the HIV viral load in HIV infected humans and results in a maintenance of CD4+ levels over those levels found in the absence of vaccination with HIV Tat, Nef or Nef-Tat and HIV gpl20.

                                                                                          This invention describes novel binding partners (A) (1) for negative factor protein (Nef) that competitively inhibit binding of calmodulin (I) to Nef, or (ii) for (I) that competitively inhibit binding of Nef to (I). (A) are used for prevention, diagnosis (by specific detection of intraand/or extra-callular Nef, including staging of infection), and/or treatment of infections with human immune deficiency virus (HIV).

This invention describes a novel retroviral packing cell (I), comprising the retroviral genes gag, pol and glycoproteins GP-1 and GP-2 of the LCWO coding gene gp, or a part of these. The products of the invention have anti-HIV and cytostatic activity and be used for gene therapy. (I) is useful for in vitro infection of cells, especially hematopoletic stem cells, for expression of transgenes in cells and as a pharmaceutical carrier for gene therapy. (I) is therefore useful in the treatment of infectious diseases (HIV or AIDS), neoplasms (carcinomas), melanomas and other diseases. This sequence represents the Human immunodeficiency virus (HIV-1) nef protein described in the method of the invention.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           121 FPDWQNYTPGPGVRYPLTFGWCYKLVPVEPDKVEEANKGENTSLLHPVSLHGMDDPEREV 180

                                                                                                                    The nef protein comprises peptides which are expressed in vivo in HIV infected patients before detectable amts. of p25, gpl10 and gp41 are expressed. Thus, they can be used in assays for early detection of HIV. They can also be used to raise antibodies for use in detection, to induce cellular immunity or to raise neutralising antibodies that either inactivate the AIDS virus or reduce the viability of the virus in vivo or destroy infected cells. The peptides may be used in viral vaccines.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  New retroviral packing cell useful as pharmaceutical carrier in gene therapy for treatment of HIV and neoplasms, comprises retroviral genes

                          an isolated
                      The invention relates to an antigenic composition comprising an isolated primate lentivirus whose genome contains an engineered non-revertible null mutation in the nef gene, or an infectious DNA clone in a carrier. The antigenic composition is used in vaccines against infection by the lentivirus, e.g. AIDS.
                                                                                                                                                                      120
                                                                                                                                                                                180
                                                                                                                                                                                                                  A comparison of AAN60287 with the CDNA of the HTLV-III genome revealed one particular clone, designated p7.11 which contained a DNA sequence encoding this peptide (AAP60308) sequence. This approx. 2.2 kilobase covers the precursor gag region and encodes, 5' to 3',

This invention describes a novel-fusion polypeptide which comprises (a) a first polypeptide sequence of an AIDS associated E', env, or gag polypeptide that the sequence of an AIDS associated E', env, or gag second polypeptide sequence which is not an AIDS associated vitus polypeptide sequence which is not an AIDS associated vitus polypeptide are are (1) a fusion polypeptide having a charge simplex virus (HSV) gD signal peptide sequence fused in reading a rame with a polypeptide sequence other than HSV gD, (2) a nucleic acid encoding a fusion polypeptide as in (1); (3) an expression vector comprising a nucleic acid as in (2); (4) a host comprising a vector as in (3). The AIDS-associated fusion polypeptides can be used in the detection of and vaccination against viral etiological agents of AIDS. They can also be administered as a pharmaceutical agent to inhibit infection by AIDS associated retrovirus or dissemination of such
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         DNA vaccine; codon optimisation; Nef protein; HIV infection; anti-HIV; cell mediated immune response; cytotoxic T lymphocyte; CTL; human immunodeficiency virus-1; HIV-1; mutant; mutein.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         PPDWQNYTPGPGVRYPLTFGWCYKLVPVEPDKVEEANKGENTSLLHPVSLHGMDDPEREV 180

The present invention relates to a DNA vaccine comprising a DNA expression vector, and a DNA molecule containing a codon optimised open reading frame encoding a Nef protein or its immunogenic derivative. The Nef protein or its derivative is expressed and generates an immune caponse which provides a substantial level of protection against HIV infection, upon administration of to a host. The DNA vaccine is useful for inducing a cell mediated immune (cytocoxic T lymphocyte, CTL) response against infection or disease caused by virulent strains of HIV, copy administrating the DNA vaccine into the tissue of the vertebrate host, preferably human. It is also useful for lowering transmission rate to previously uninfected individual, so as to prolong the asymptomatic phase of HIV infection. The present sequence is human immunodeficiency virus-1 (HIV-1) iffl Nef protein. The different codon optimised nef
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       ä

This sequence represents a protein of unspecified function contained in a complete nucleotide sequence of ARV-2 derived from partial sequences of several ARV clones. The invention provides a method for construction of a sector for expression of a polypeptide in a mammalian cell, comprising a polypeptide coding sequence operably linked downstream of an enhanced promoter. The enhanced promoter comprises the human cytomegalovirus immediate early region (HCMV IEI) promoter and the first intron proximate to the 3' end of the HCMV IEI) promoter. The polypeptide can be any of the HIV recombinant polypeptides and especially HIV gpl20. Expression of HIV gpl20 by CoS 7 cells transfected with pCMMs containing the gpl20 coding region, where pCMMs is a vector containing the above enhanced promoter, is increased by a factor of 50-100 compared with the use of a vector containing the use of a vector
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                57 WLEAQEEEEVGFPVTPQVPLRPMTYKAAVDLSHFLKEKGGLEGLIHSQRRQDILDLWIYH 116

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           Seguence
                                                                  AAE04962;
                                                                                                                                                                                                                                   Human
                   AAE04962
                                                                ä
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  The invention relates to the improvement of HIV-1 immunoassays by the use of an HIV-1 antigen comprising an immunogenic fragment of recombinant or synthetic HIV-1 pol, which is encoded by an approximately 9.7 kb sequence between a BatXI restriction site at position 3006 and an NdeI site at position 5131 of the genome (the proviral DNA sequence is given in AAZ90201). The immunogenic pol fragment is not immunologically cross reactive with human T cell lymphotropic viruses I or II. The invention also encompasses the used of p31 as an antigen. The recombinant antigen may be produced in Escherichia coli, Saccharomyces cerevisiae or in mammalian cells. Immunoassays using the recombinant HIV proteins may be used to diagnose and stage HIV-1 infections. Sequences

The present invention relates to a DNA vaccine comprising a DNA expression vector, and a DNA molecule containing a codon optimised open reading frame encoding a Nef protein or its immunogenic derivative. The Nef protein or its derivative is expressed and generates an immune response which provides a substantial level of protection against HIV infection, upon administration of to a host. The DNA vaccine is useful for inducing a cell mediated immune (cytotoxic T lymphocyte, CTL) cresponse against infection or disease caused by virulent strains of HIV, by administering the DNA vaccine into the tissue of the vertebrate host, preferably human. It is also useful for lowering transmission rate to previously uninfected individuals and/or for reducing levels of viral loads within an infected individuals, so as to prolong the asymptomatic phase of HIV infection. The present sequence is human immunodeficiency virus-1 (HIV-1) jrfl Nef (GZA, LLAA) mutant protein. The different nef
                                                                           Novel DNA vaccine useful for inducing cell mediated immune response against virulent strains of HIV, comprises DNA expression vector, and DNA containing codon optimized open reading frame encoding Nef protein
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        Virus-1 (HIV-1) Jrfl Nef (G2A, LLAA) mutant protein. The different nef constructs of the invention are used in the exemplification of the

The present invention relates to a DNA vaccine comprising a DNA expression vector, and a DNA molecule containing a codon optimised open reading frame encoding a Net protein or its immunogenic derivative. The Net protein or its derivative is expressed and generates an immune response which provides a substantial level of protection against HIV infection, upon administration of to a host. The DNA vaccine is useful for inducing a cell mediated immune (cytotoxic T lymphocyte, CTL) response against infection or disease caused by virulent strains of HIV, by administering the DNA vaccine into the tissue of the vertebrate host, by administering the DNA vaccine into the tissue of the vertebrate host, preferably human. It is also useful for lowering transmission rate to previously unifected individual, so as to prolong the asymptomatic phase of HIV infection. The present sequence is human tissue plasminogen action and the myristylation site (G1y2) in the HIV-1 jifl Nef (opt thanef) chimeric mutant protein. The mutation include deletion of the myristylation site (G1y2) in the HIV-1 jifl Nef protein. The different codon optimised nef constructs of the invention are used
                                                                                                                                                                         Novel DNA vaccine useful for inducing cell mediated immune response against virulent strains of HIV, comprises DNA expression vector, and DNA containing codon optimized open reading frame encoding Nef protein
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     29; Page 17; 84pp; English.

the procession vector, and a DNA molecule containing a codon optimised open reading frame encoding a Nef protein or its immunogenic derivative. The protein or its derivative is expressed and generates an immune response which provides a substantial level of protection against HIV infection, upon administration of to a host. The DNA vaccine is useful for inducing a cell mediated immune (cytotoxic T lymphocyte, CTL) by administering the DNA vaccine into the tissue of the vertebrate host, by administering the DNA vaccine into the tissue of the vertebrate host, by administering the DNA vaccine into the tissue of the vertebrate host, by administering the DNA vaccine into the tissue of the vertebrate host, by administering the DNA vaccine into the tissue of the vertebrate to previously uninfected individuals and/or for reducing levels of viral loads within an infected individual, so as to prolong the asymptomatic phase of HIV infection. The present sequence is human tissue plasminogen activator (tPA) leader peptide human immunodeficiency virus-1 (HIV-1) if Nef (LLAA) chimeric mutant protein. The different codon optimised nef constructs of the invention are used in the exemplification
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        ä

                                                                                                for a
                                                                                           The present in invention provides the protein and coding sequences for a number of human immunodeficiency virus (HIV) type 1 non-subtype B isolates. The sequences shown include the near full-length coding sequences from each isolate, and the env, pol, vif, vpr, vpu, gag, tat, rev and nef proteins. These can be used to detect the presence of HIV-1 in a sample and to produce antibodies against non-subtype B HIV-1 virus. These antibodies can be used in vaccines to prevent and treat HIV
                                                                                                                                                                                                                                                                                                                                                                                                  61 QEEEEVGFPVTPQVPLRPMTYKAAVDLSHFLKEKGGLEGLIHSQRRQDILDLWIYHTQGY 120

This invention describes a novel polynucleotide isolated from human immunodeficiency virus type I subtype C/B' which can be used for the induction of specific humoral and cellular immune responses. (I) and coloded by them, are useful in pharmaceuticals.

To polypeptides (II) encoded by them, are useful in pharmaceuticals.

To human immune deficiency virus; particularly for treatment or prevention of human immune deficiency virus; particularly for treatment or prevention of human immune deficiency virus; (HIV-1) infections, also for rational design of test or therapeutic respents, or gene therapy vectors.

To Polypeptides, specially antibodies, specifically directed against (II) are similarly useful as pharmaceutical and diagnostic agents (II) are specific for intersubtype C/B' of HIV-1 so are useful in regions (particularly China and South-East Asia) where this subtype is prevalent. The products of the invention have antiviral activity. This sequence represents a protein encoded by the HIV-1 subtype C genome described in the method of the invention.

No. is the number of results predicted by chance to have a score greater than or equal to the score of the result being printed, and is derived by analysis of the total score distribution.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       Sequence 43,
